

Future of Water Security

Nisreen Lahham

PIP Convening – Rabat 2016

Outline

- Water Security- Driving Forces
- Future Trends
- Responses/ Emerging Interventions
- The Nexus Approach

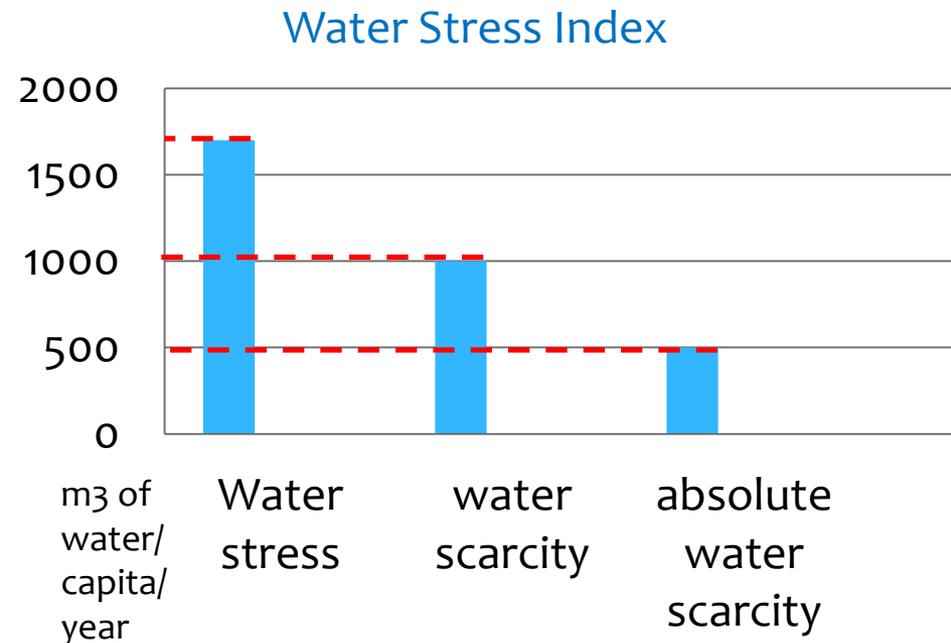

Water Security

“The capacity of a population to safeguard sustainable **access** to **adequate quantities** of **acceptable quality water** for sustaining livelihoods, human well-being, and socio-economic **development**”. (UN-Water, 2013).

2030 Agenda for Sustainable Development

Goal 6: Ensure availability and sustainable management of water and sanitation for all

Water Stress Index: defines water scarcity for countries in terms of the total water resources available for each person in the country.

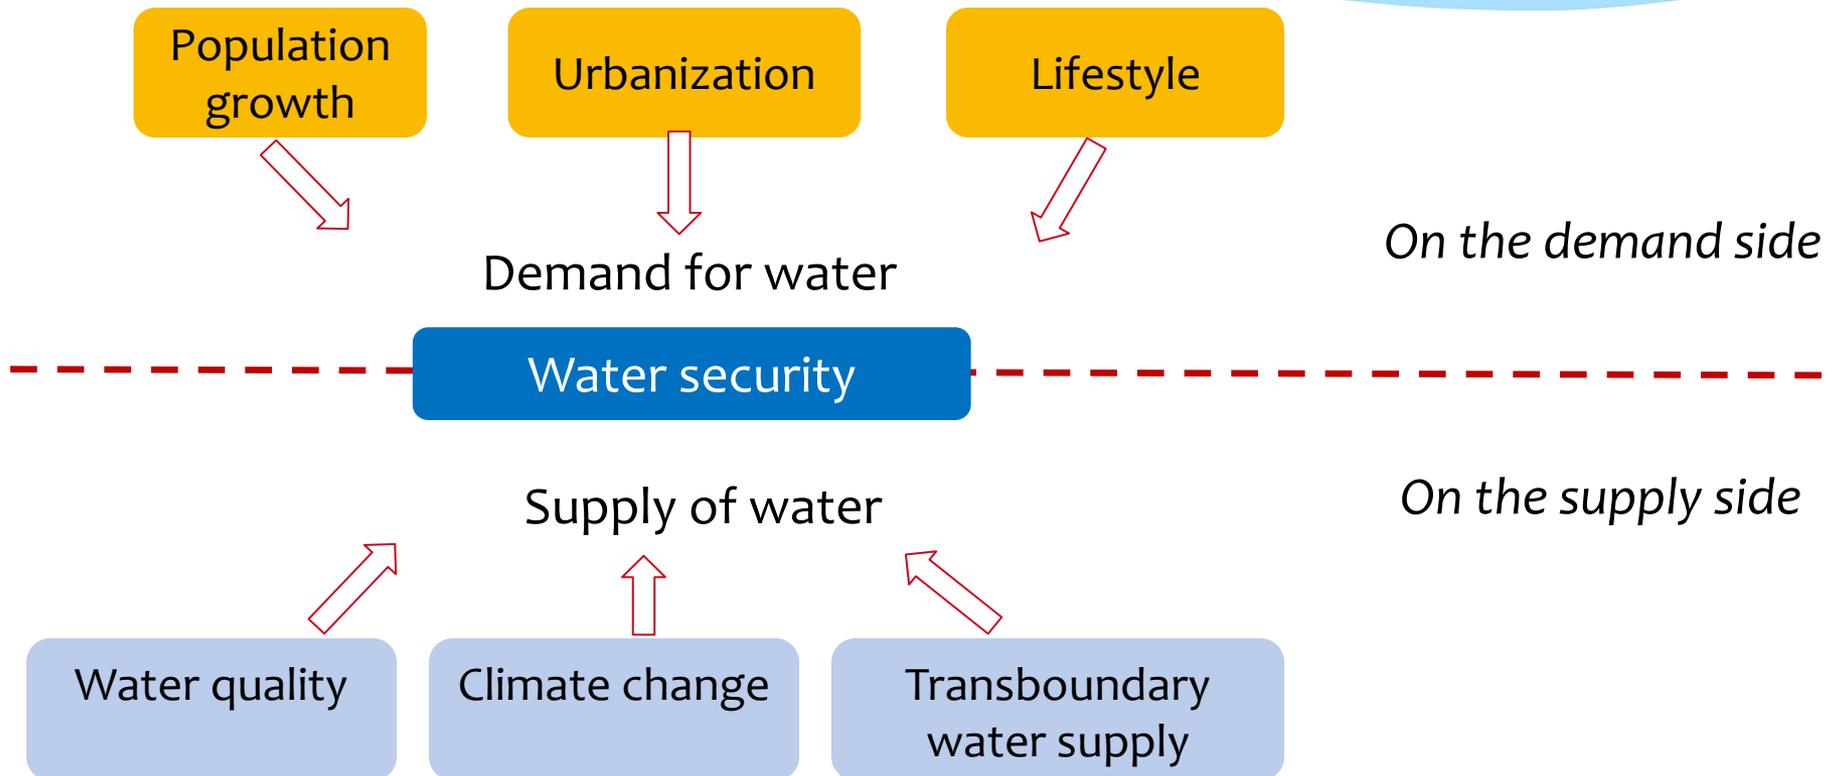

Water Scarcity Worldwide

- The world is already in a critical situation of water scarcity- Millions of people are suffering from water shortages.
- 1/3 of humanity does not have enough water.
- 1.1 billion people have no access to clean drinking water.

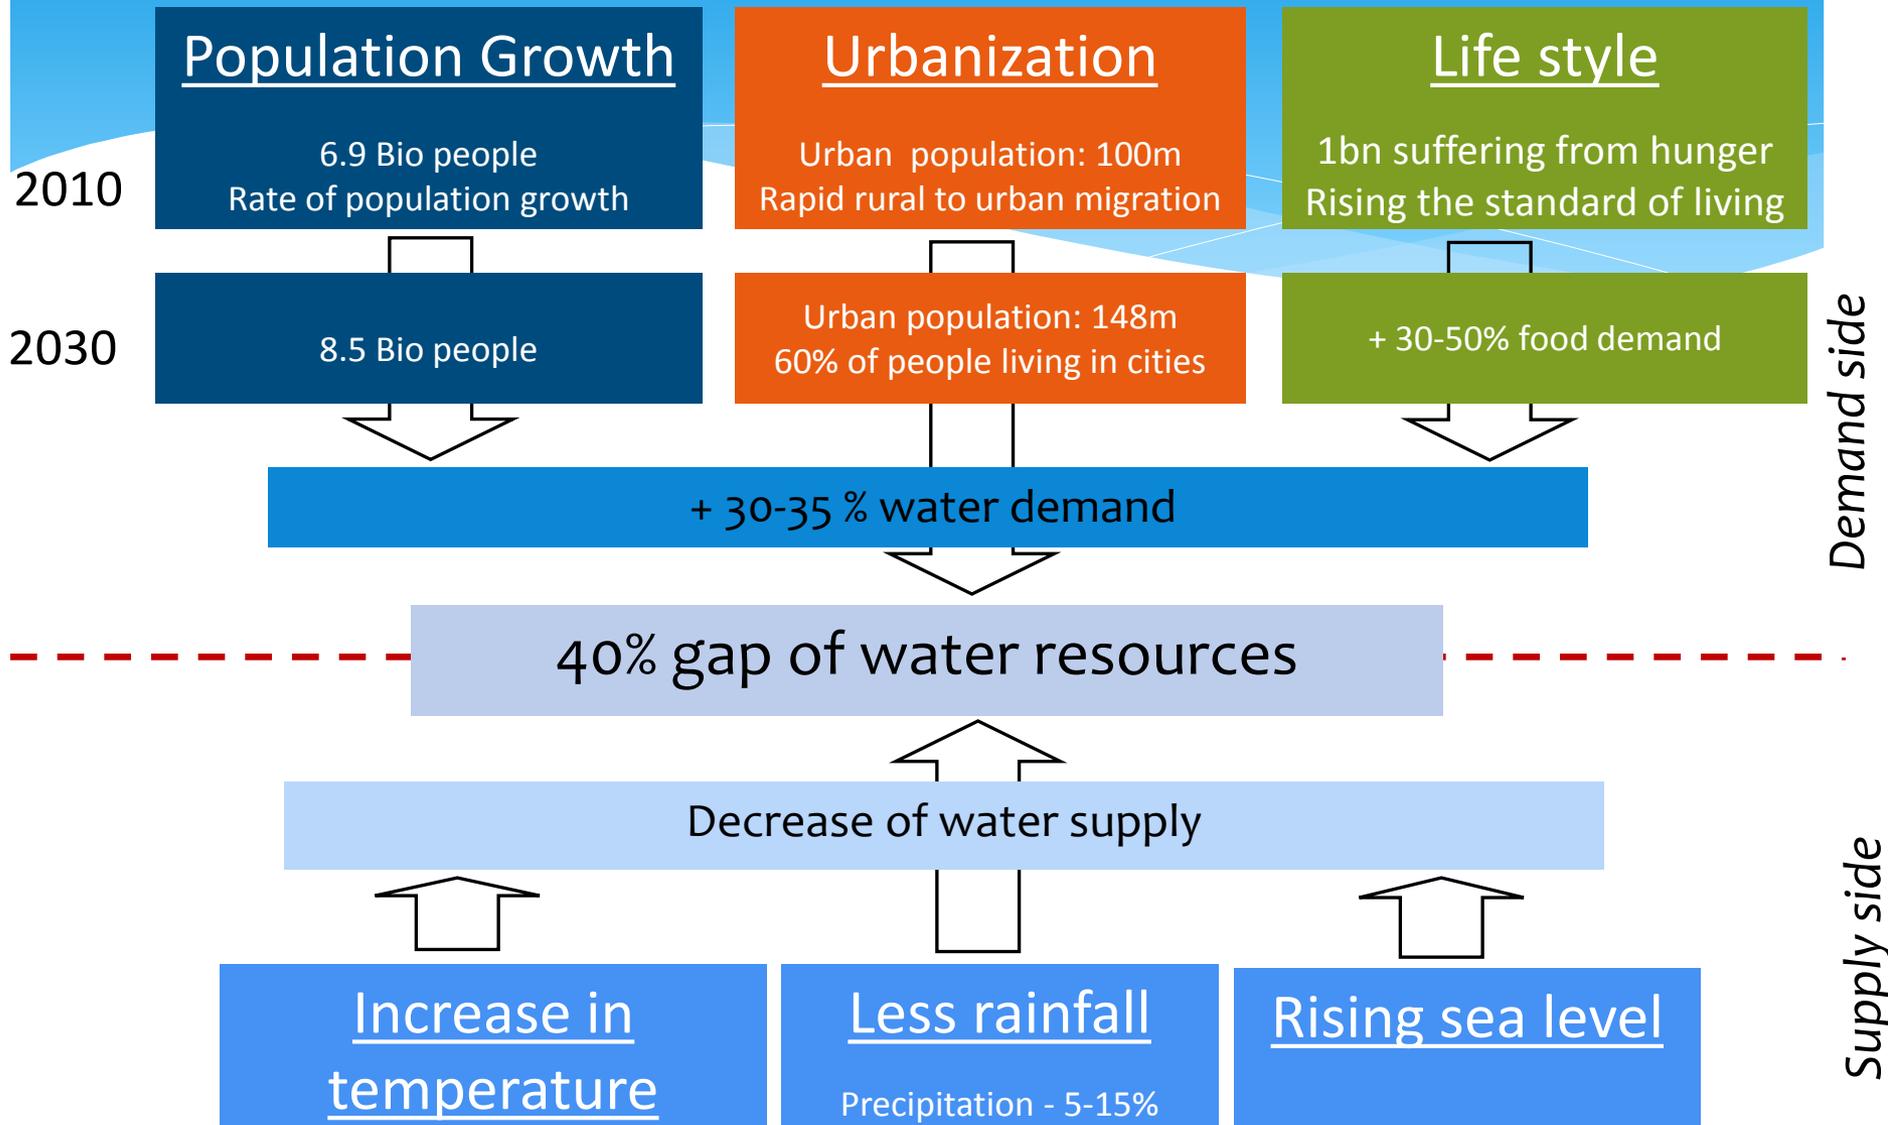

Driving Forces of Water Security

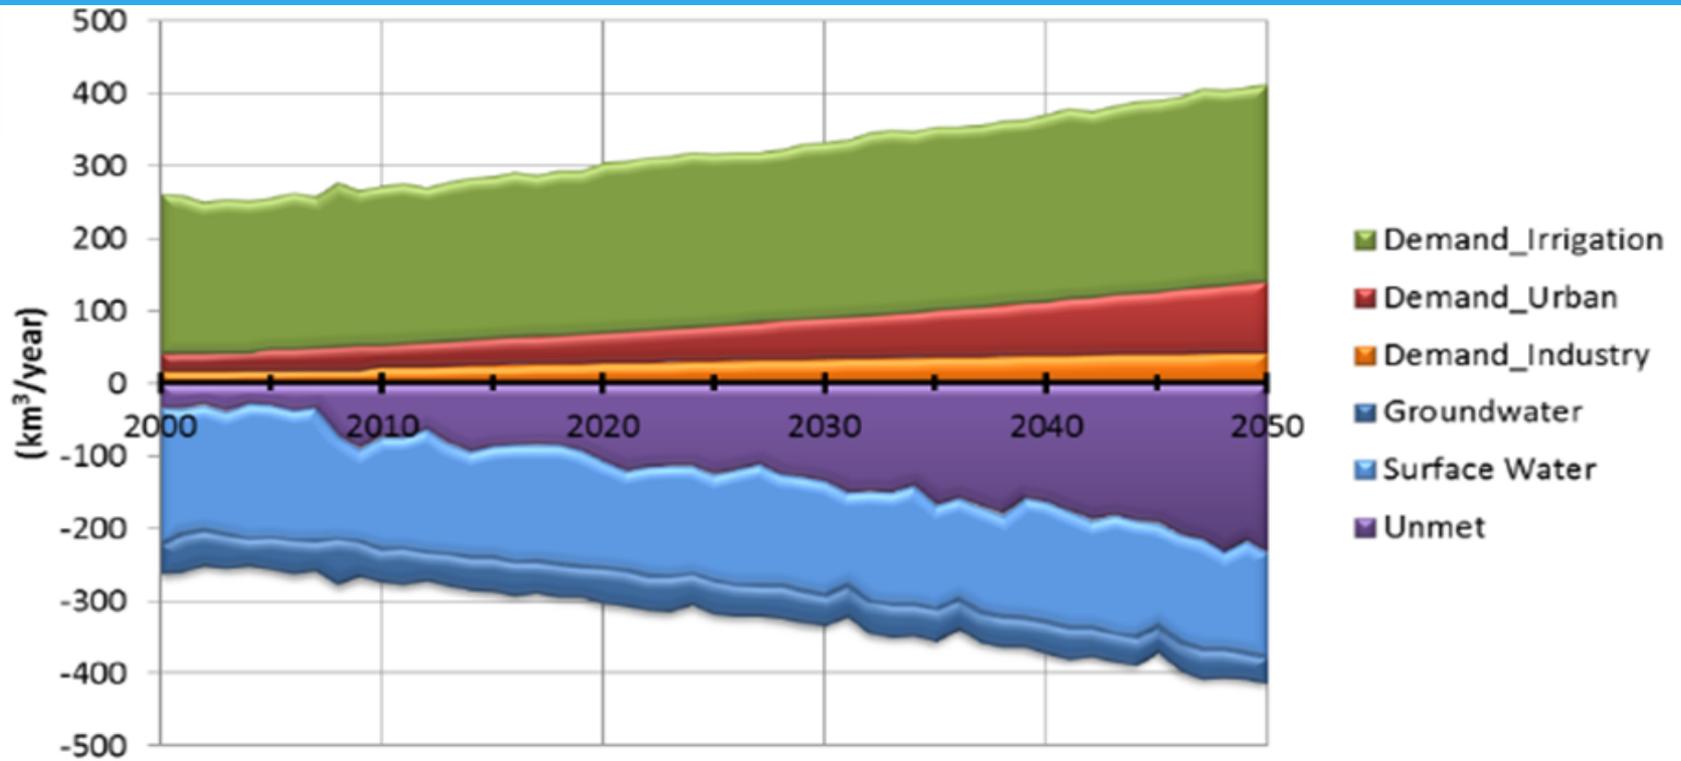

The future of water security will be determined by the driving forces

Future Trends

Future Water gap in the Arab Region

Water demand and supply in the Arab Region base on climate change scenario AVG (WB)

Water demand +25 % in 2030 - + 60% in 2050.

Renewable water supply -10% based on average climate change projection.

By 2050 all Arab countries will face serious rising 'unmet demand' from 16 % currently to 37 % in 2030 and 51 % in 2050.

Responses/ Emerging Interventions

Meeting demand- Managing water resources

sectors- crops pattern

Optimum
water
allocation

Embedded water

Virtual water
trade

Modernizing- reduce losses

Irrigation
technologies

Subsidize-overuse-

Water pricing

Land grab- win-win

Offshore agri.
investment

Demand for water

Water security

Management of water demand

Management of water supply

Supply of water

Mitigating
CC. effects

Renewable energy- green cities

Recycling

Reusing wastewater

Desalination

Solar used-falling prices

Water
harvesting

Collecting runoff

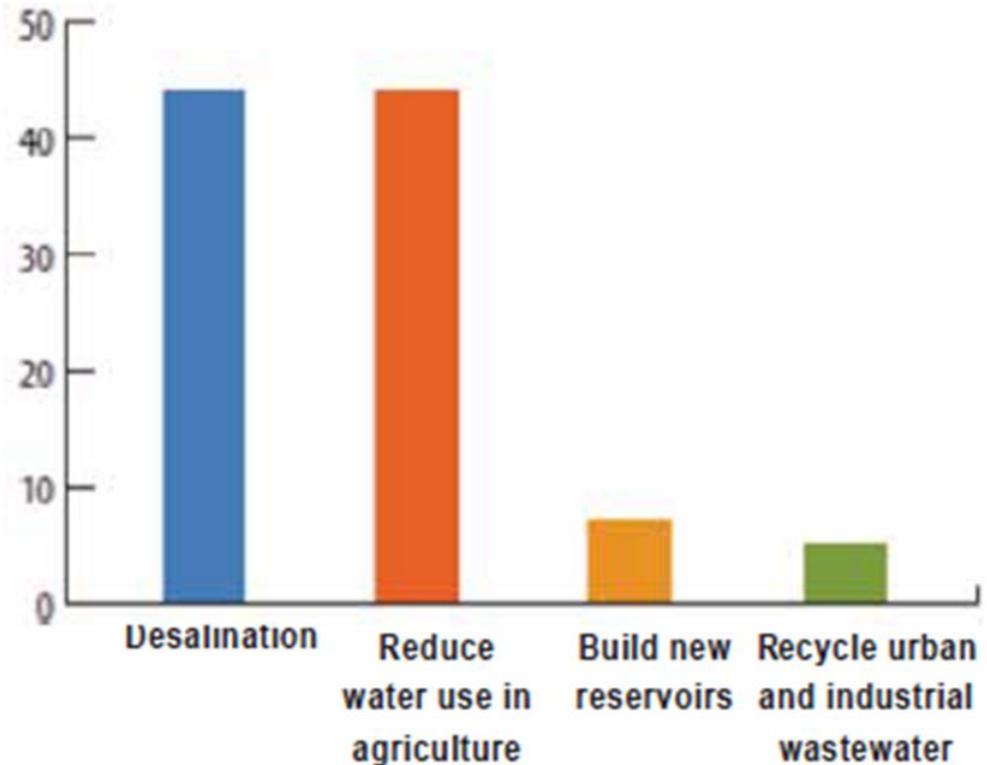

Innovative
water sources

Import water- artificial rain

Managing Water Demand

The biggest water user is agriculture, consuming 70% of the world's freshwater- A modest water savings in the agricultural sector increase significantly water available for other sectors.

Managing water demand in agriculture is likely to produce as much water as desalination by 2050.

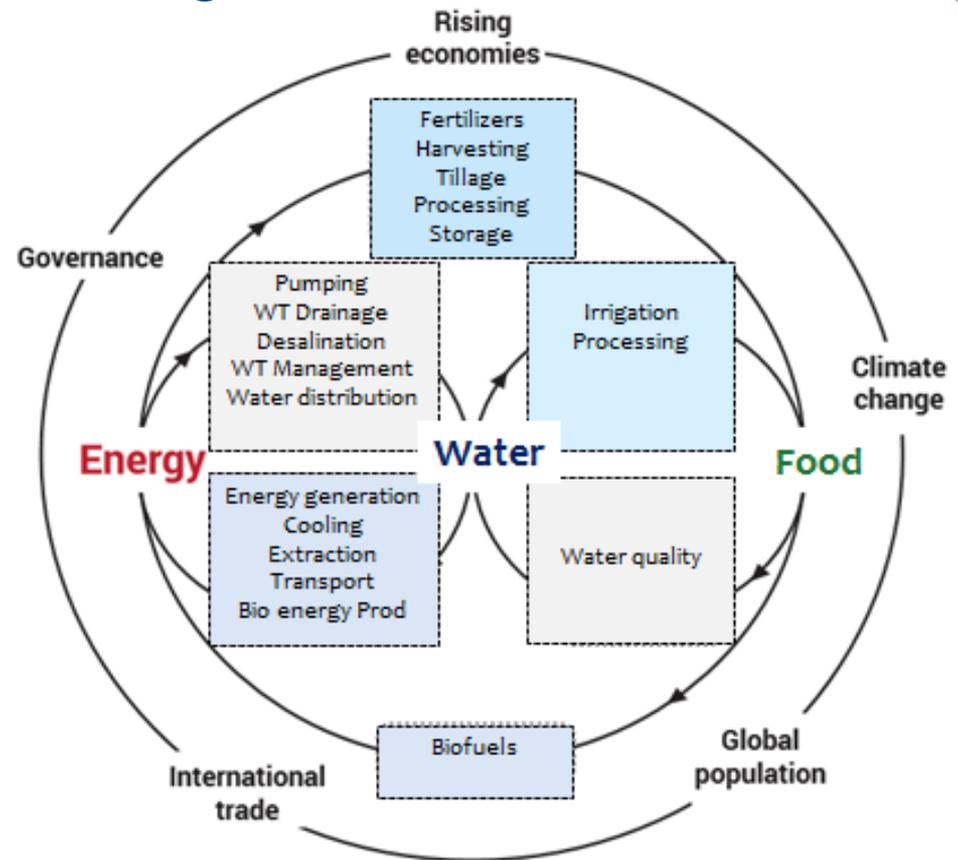

Considering the Entire Water System

The different types of water demand compete with one another—water consumed by one sector is no longer available for other.

In agriculture the return per unit water is lowest in comparison with other sectors. (re-addressing food self-sufficiency for sustainability of water).

Countries) have to reconsider water allocation across all sectors and among different development activities, where production per cubic meter of water giving maximum return; optimization of water use.

Development objectives in one sector may constrain development objectives other sectors! coordination is needed: addressing nexus trade-offs

The Nexus Approach

Considering strong interconnections of key resources

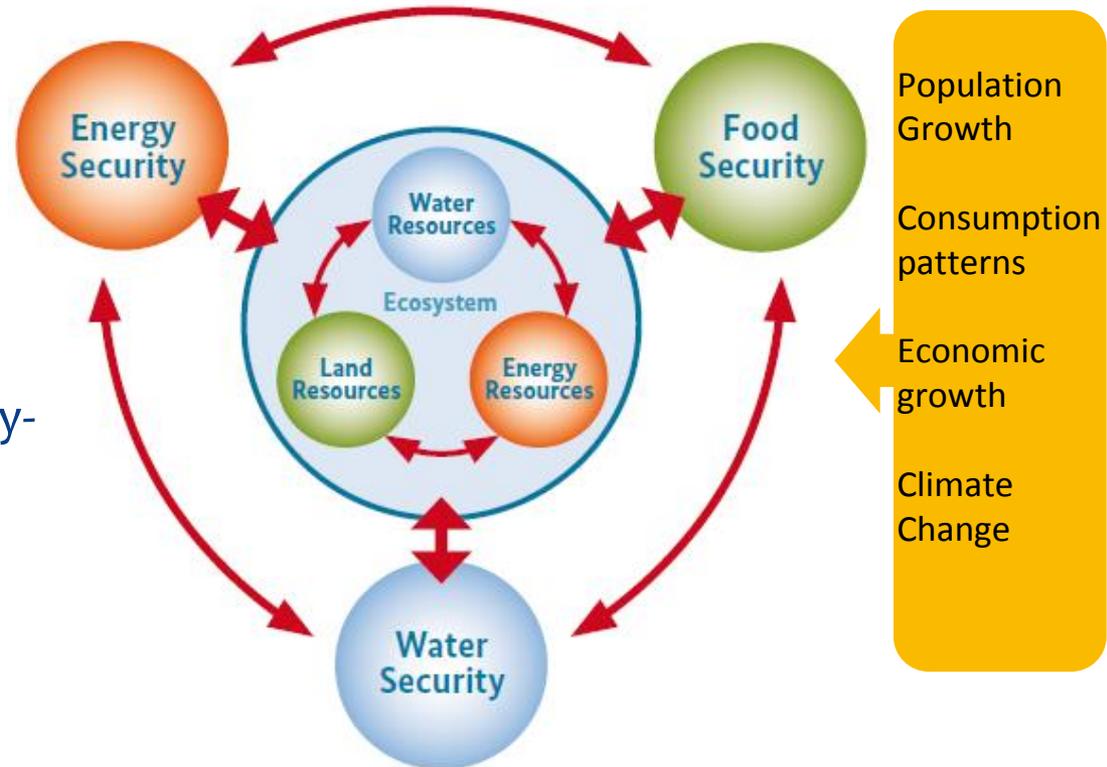

As part of the ecosystem, water, land and energy resources are interconnected.

A need for an **integrated management system** of natural resources.

Nexus as a **tool to achieve sustainable development**.

Subsidies reform for water-energy-food sectors.

LAS adopting WFE Nexus in the framework for sustainable development- **coordination- incentives- capacity building**.

A high-speed photograph of a large splash of clear blue water. The water is captured in mid-air, forming a thick, curved wall that arches from the left side towards the center. Below the main splash, a wide, shallow layer of water spreads across the bottom, filled with a dense field of small, glistening bubbles. The background is a plain, bright white, which makes the vibrant blue of the water stand out sharply.

Thank You
